Chapter 12 Exception Handling and Text IO

Motivations

When a program runs into a runtime error, the program terminates abnormally. How can you handle the runtime error so that the program can continue to run or terminate gracefully? This is the subject we will introduce in this chapter.

Objectives

- ◆ To get an overview of exceptions and exception handling (§ 12.2).
- ◆ To explore the advantages of using exception handling (§ 12.2).
- ◆ To distinguish exception types: **Error** (fatal) vs. **Exception** (nonfatal) and checked vs. unchecked (§ 12.3).
- ◆ To declare exceptions in a method header (§ 12.4.1).
- ◆ To throw exceptions in a method (§ 12.4.2).
- **→** To write a **try-catch** block to handle exceptions (§ 12.4.3).
- ◆ To explain how an exception is propagated (§ 12.4.3).
- **→** To obtain information from an exception object (§ 12.4.4).
- ◆ To develop applications with exception handling (§ 12.4.5).
- → To use the **finally** clause in a **try-catch** block (§ 12.5).
- ◆ To use exceptions only for unexpected errors (§ 12.6).
- **→** To rethrow exceptions in a **catch** block (§ 12.7).
- → To create chained exceptions (§ 12.8).
- ◆ To define custom exception classes (§ 12.9).
- ◆ To discover file/directory properties, to delete and rename files/directories, and to create directories using the **File** class (§ 12.10).
- → To write data to a file using the **PrintWriter** class (§ 12.11.1).
- ◆ To use try-with-resources to ensure that the resources are closed automatically (§ 12.11.2).
- → To read data from a file using the **Scanner** class (§ 12.11.3).
- ◆ To understand how data is read using a **Scanner** (§ 12.11.4).
- ◆ To develop a program that replaces text in a file (§ 12.11.5).
- ◆ To read data from the Web (§ 12.12).
- → To develop a Web crawler (§ 12.13).

Exception-Handling Overview

Show runtime error

Quotient

Fix it using an if statement

QuotientWithIf

With a method

QuotientWithMethod

Exception Advantages

QuotientWithException

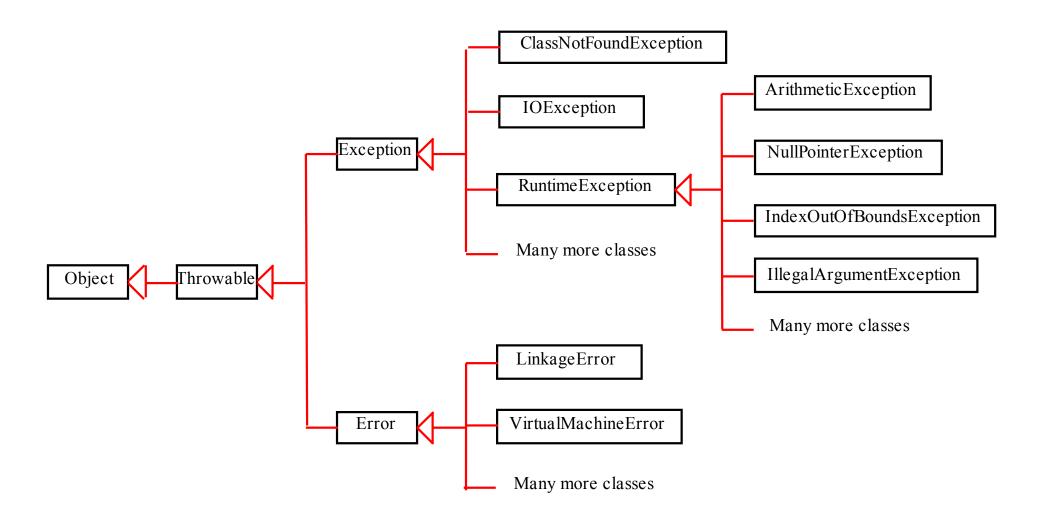

Now you see the *advantages* of using exception handling. It enables a method to throw an exception to its caller. Without this capability, a method must handle the exception or terminate the program.

Handling InputMismatchException

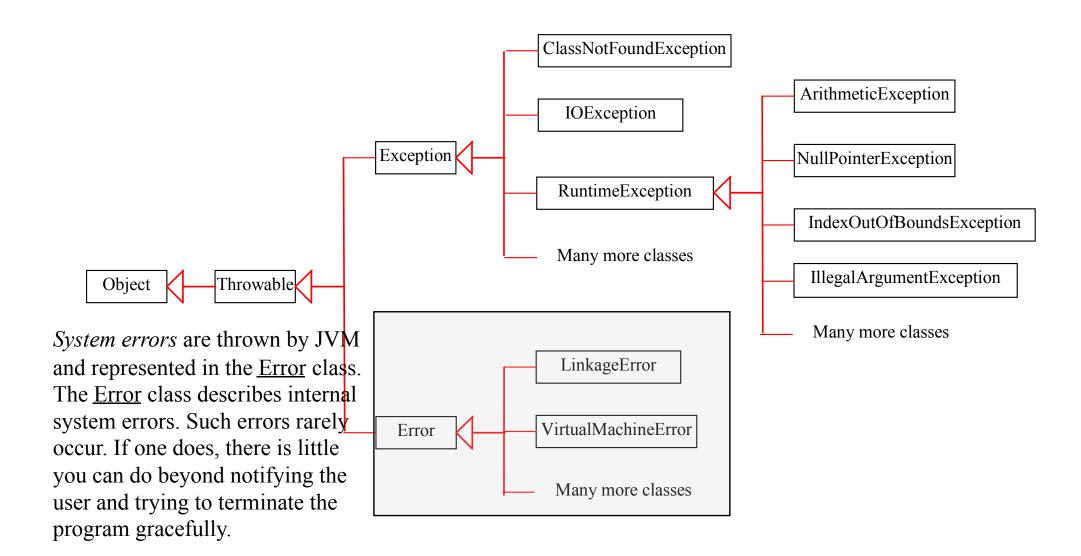

<u>InputMismatchExceptionDemo</u>

By handling InputMismatchException, your program will continuously read an input until it is correct.

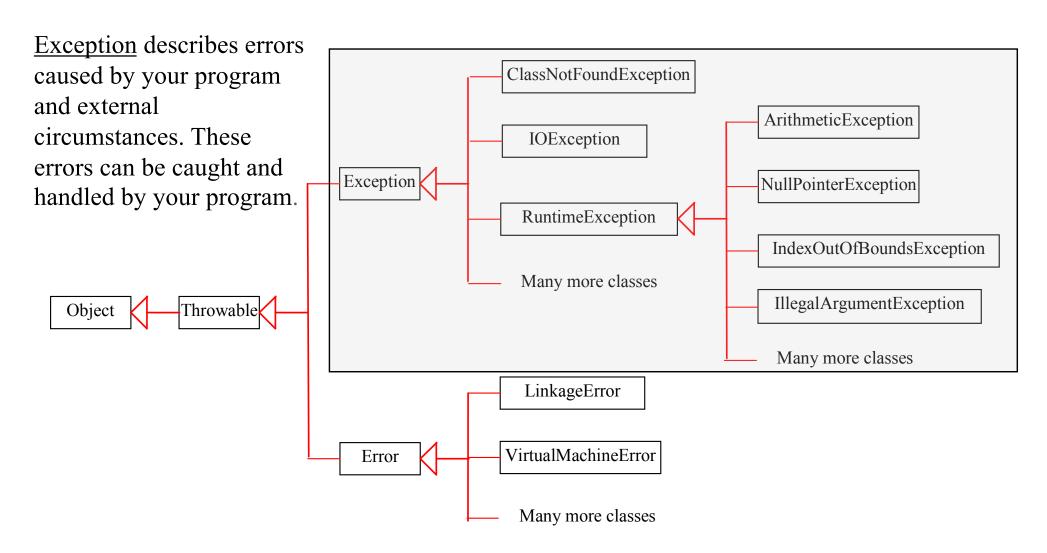

Exception Types

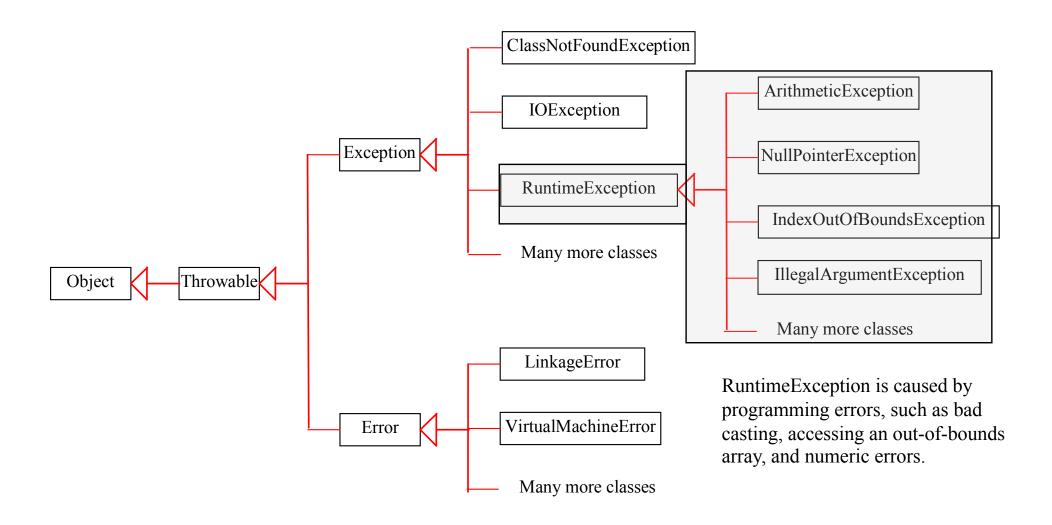

System Errors

Exceptions

Runtime Exceptions

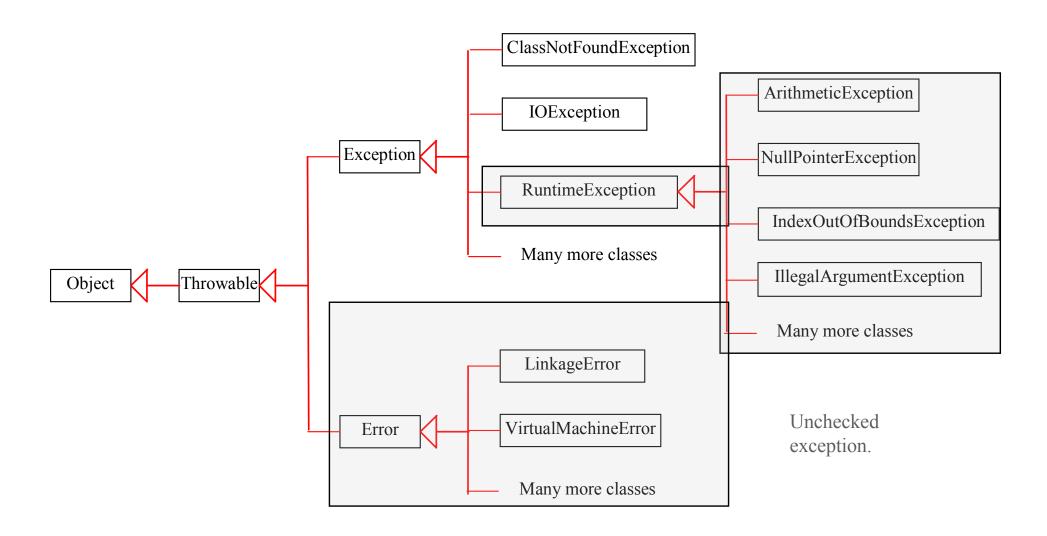

Checked Exceptions vs. Unchecked Exceptions

RuntimeException, Error and their subclasses are known as *unchecked exceptions*. All other exceptions are known as *checked exceptions*, meaning that the compiler forces the programmer to check and deal with the exceptions.

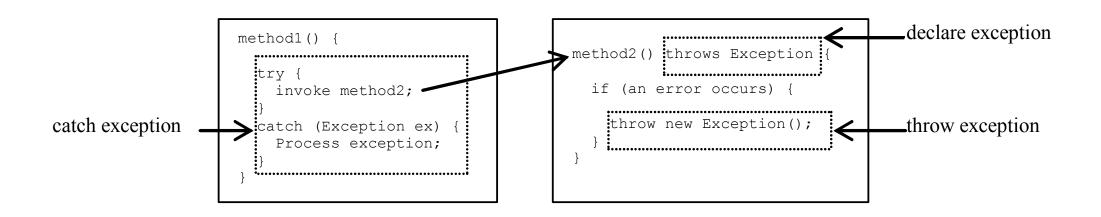

Unchecked Exceptions

In most cases, unchecked exceptions reflect programming logic errors that are not recoverable. For example, a NullPointerException is thrown if you access an object through a reference variable before an object is assigned to it; an IndexOutOfBoundsException is thrown if you access an element in an array outside the bounds of the array. These are the logic errors that should be corrected in the program. Unchecked exceptions can occur anywhere in the program. To avoid cumbersome overuse of try-catch blocks, Java does not mandate you to write code to catch unchecked exceptions.

Unchecked Exceptions

Declaring, Throwing, and Catching Exceptions

Declaring Exceptions

Every method must state the types of checked exceptions it might throw. This is known as *declaring exceptions*.

public void myMethod()
throws IOException

public void myMethod()
 throws IOException, OtherException

Throwing Exceptions

When the program detects an error, the program can create an instance of an appropriate exception type and throw it. This is known as *throwing an exception*.

throw new TheException();

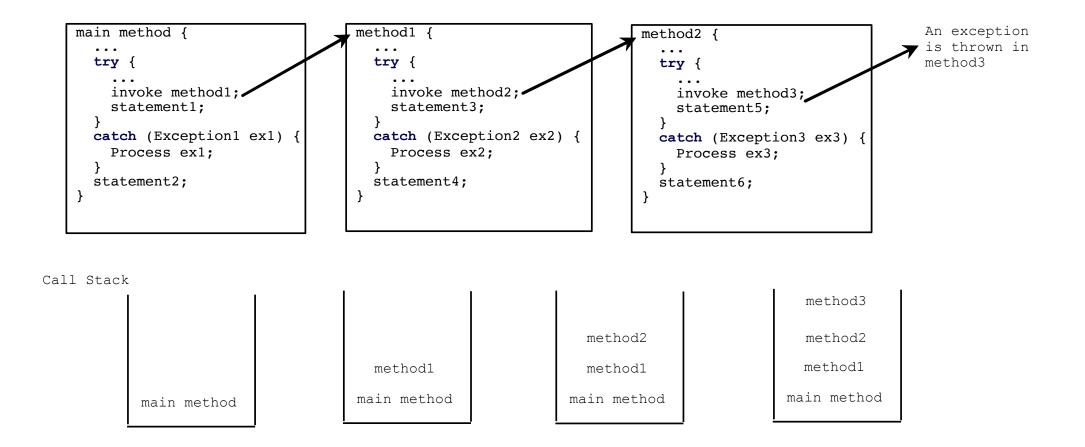

TheException ex = new TheException(); throw ex;

Throwing Exceptions Example

Catching Exceptions

```
try {
   statements; // Statements that may throw exceptions
}
catch (Exception1 exVar1) {
   handler for exception1;
}
catch (Exception2 exVar2) {
   handler for exception2;
}
...
catch (ExceptionN exVar3) {
   handler for exceptionN;
}
```

Catching Exceptions

Catch or Declare Checked Exceptions

Suppose p2 is defined as follows:

```
void p2() throws IOException {
  if (a file does not exist) {
    throw new IOException("File does not exist");
  }
  ...
}
```

Catch or Declare Checked Exceptions

Java forces to deal with checked exceptions. If a method declares a checked exception (i.e., an exception other than <u>Error</u> or <u>RuntimeException</u>), you must invoke it in a <u>try-catch</u> block or declare to throw the exception in the calling method. For example, suppose that method <u>p1</u> invokes method <u>p2</u> and <u>p2</u> may throw a checked exception (e.g., <u>IOException</u>), you have to write the code as shown in (a) or (b).

```
void p1() {
  try {
     p2();
  }
  catch (IOException ex) {
     ...
  }
}
```

```
void p1() throws IOException {
  p2();
}
```

(b)

Example: Declaring, Throwing, and Catching Exceptions

◆ Objective: This example demonstrates declaring, throwing, and catching exceptions by modifying the <u>setRadius</u> method in the <u>Circle</u> class defined in Chapter 8. The new <u>setRadius</u> method throws an exception if radius is negative.

<u>TestCircleWithException</u>

<u>CircleWithException</u>

Information from Exception

java.lang.Throwable

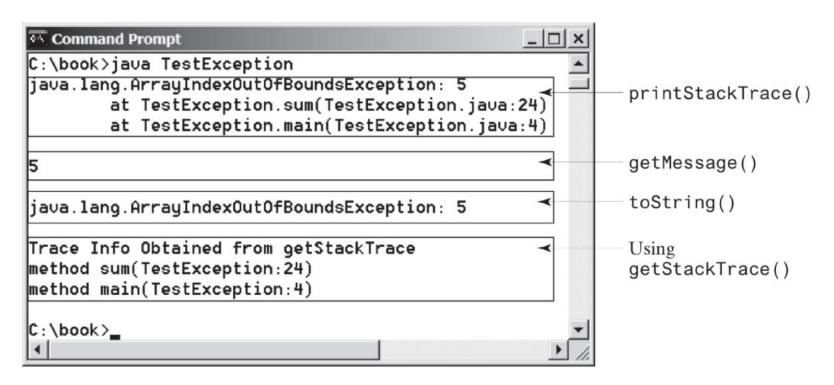

+getMessage(): String

+toString(): String

+printStackTrace(): void

+getStackTrace(): StackTraceElement[]

TestException

Rethrowing Exceptions

```
try {
   statements;
}
catch(TheException ex) {
   perform operations before exits;
   throw ex;
}
```

The finally Clause

```
try {
  statements;
catch(TheException ex) {
 handling ex;
finally {
  finalStatements;
```

Suppose no exceptions in the statements

```
try {
  statements;
catch(TheException ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
The final block is
                                  always executed
try {
  statements;
catch(TheException ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
Next statement in the
                                  method is executed
try {
  statements;
catch(TheException ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
Suppose an exception
try {
                                        of type Exception1 is
  statement1;
                                        thrown in statement2
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
The exception is
try {
                                       handled.
  statement1;
  statement2;
  statement3;
catch (Exception1 ex)
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
The final block is
try {
                                       always executed.
  statement1;
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
The next statement in
try {
                                        the method is now
  statement1;
                                        executed.
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
finally {
  finalStatements;
Next statement;
```

```
try {
  statement1;
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
catch(Exception2 ex) {
  handling ex;
  throw ex;
finally {
  finalStatements;
Next statement;
```

statement2 throws an exception of type Exception2.

```
try {
                                          Handling exception
  statement1;
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
catch(Exception2 ex)
  handling ex;
  throw ex;
finally {
  finalStatements;
Next statement;
```

```
try {
                                          Execute the final block
  statement1;
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
catch(Exception2 ex) {
  handling ex;
  throw ex;
finally {
  finalStatements;
Next statement;
```

```
try {
  statement1;
  statement2;
  statement3;
catch(Exception1 ex) {
  handling ex;
catch(Exception2 ex) {
  handling ex;
  throw ex;
finally {
  finalStatements;
Next statement;
```

Rethrow the exception and control is transferred to the caller

With finally

Decouple try/catch and try/finally

```
InputStream in = . . .;
try
  try
     code that might throw exceptions
  finally
     in.close();
catch (IOException e)
  show error message
```

MainCatcherNew

Cautions When Using Exceptions

★ Exception handling separates error-handling code from normal programming tasks, thus making programs easier to read and to modify. Be aware, however, that exception handling usually requires more time and resources because it requires instantiating a new exception object, rolling back the call stack, and propagating the errors to the calling methods.

When to Throw Exceptions

★ An exception occurs in a method. If you want the exception to be processed by its caller, you should create an exception object and throw it. If you can handle the exception in the method where it occurs, there is no need to throw it.

When to Use Exceptions

When should you use the try-catch block in the code? You should use it to deal with unexpected error conditions. Do not use it to deal with simple, expected situations. For example, the following code

```
try {
    System.out.println(refVar.toString());
}
catch (NullPointerException ex) {
    System.out.println("refVar is null");
}
```

When to Use Exceptions

is better to be replaced by

if (refVar != null)
 System.out.println(refVar.toString());
else
 System.out.println("refVar is null");

Chained Exception

Add information by rethrowing a new capsulated Exception

ChainedExceptionDemo

Defining Custom Exception Classes

- → Use the exception classes in the API whenever possible.
- → Define custom exception classes if the predefined classes are not sufficient.
- → Define custom exception classes by extending Exception or a subclass of Exception.

Custom Exception Class Example

the <u>setRadius</u> method throws an exception if the radius is negative. Suppose you wish to pass the radius to the handler, you have to create a custom exception class.

<u>InvalidRadiusException</u>

<u>CircleWithRadiusException</u>

<u>TestCircleWithRadiusException</u>

Tips for Using Exceptions

- 1.Exception handling is not supposed to replace a simple test.
- 2.Do not micromanage exceptions.
- 3. Make good use of the exception hierarchy.
- 4.Do not squelch exceptions.
- 5. When you detect an error, "tough love" works better than indulgence.
- 6. Propagating exceptions is not a sign of shame.

From Core Java Vol 1

```
public Image loadImage(String s)
{
    try
    {
        // code that threatens to throw checked exceptions
    }
    catch (Exception e)
        {} // so there
}
```

Should Stack.pop return null, or throw an exception when a stack is empty?

We think it is better to throw a *EmptyStackException* at the point of failure than to have a *NullPointerException* occur at later time.

The File Class

The <u>File</u> class is intended to provide an abstraction that deals with most of the machine-dependent complexities of files and path names in a machine-independent fashion. The filename is a string. The <u>File</u> class is a wrapper class for the file name and its directory path.

Obtaining file properties and manipulating file

java.io.File +File(pathname: String) Creates a File object for the specified path name. The path name may be a directory or a file. +File(parent: String, child: String) Creates a File object for the child under the directory parent. The child may be a file name or a subdirectory. Creates a File object for the child under the directory parent. The parent is a +File(parent: File, child: String) File object. In the preceding constructor, the parent is a string. +exists(): boolean Returns true if the file or the directory represented by the File object exists. +canRead(): boolean Returns true if the file represented by the File object exists and can be read. +canWrite(): boolean Returns true if the file represented by the File object exists and can be written. +isDirectory(): boolean Returns true if the File object represents a directory. +isFile(): boolean Returns true if the File object represents a file. +isAbsolute(): boolean Returns true if the File object is created using an absolute path name. +isHidden(): boolean Returns true if the file represented in the File object is hidden. The exact definition of hidden is system-dependent. On Windows, you can mark a file hidden in the File Properties dialog box. On Unix systems, a file is hidden if its name begins with a period(.) character. Returns the complete absolute file or directory name represented by the File +getAbsolutePath(): String object. +getCanonicalPath(): String Returns the same as getAbsolutePath() except that it removes redundant names, such as "." and "..", from the path name, resolves symbolic links (on Unix), and converts drive letters to standard uppercase (on Windows). +getName(): String Returns the last name of the complete directory and file name represented by the File object. For example, new File ("c:\\book\\test.dat").getName() returns +getPath(): String Returns the complete directory and file name represented by the File object. For example, new File("c:\book\test.dat").getPath() returns c:\book\test.dat. +getParent(): String Returns the complete parent directory of the current directory or the file represented by the File object. For example, new File("c:\\book\\test.dat").getParent() returns c:\book. +lastModified(): long Returns the time that the file was last modified. +length(): long Returns the size of the file, or 0 if it does not exist or if it is a directory. +listFile(): File[] Returns the files under the directory for a directory File object. +delete(): boolean Deletes the file or directory represented by this File object. The method returns true if the deletion succeeds. +renameTo(dest: File): boolean Renames the file or directory represented by this File object to the specified name represented in dest. The method returns true if the operation succeeds. +mkdir(): boolean Creates a directory represented in this File object. Returns true if the the directory is created successfully. +mkdirs(): boolean Same as mkdir() except that it creates directory along with its parent directories if the parent directories do not exist.

Problem: Explore File Properties

Objective: Write a program that demonstrates how to create files in a platform-independent way and use the methods in the File class to obtain their properties. The following figures show a sample run of the program on Windows and on Unix.

```
Command Prompt
C:\book>java TestFileClass
Does it exist? true
Can it be read? true
Can it be written? true
Is it a directory? false
Is it a file? true
Is it absolute? false
Is it hidden? false
What is its absolute path? C:\book\.\image\us.gif
What is its canonical path? C:\book\image\us.gif
What is its name? us.gif
What is its path? .\image\us.gif
When was it last modified? Sat May 08 14:00:34 EDT 1999
What is the path separator? ;
What is the name separator? \
C:\book>
```

```
_ | □ | ×
Command Prompt - telnet panda
/home/liang/book
💲 java TestFileClass
Does it exist? true
Can it be read? true
Can it be written? true
Is it a directory? false
Is it a file? true
Is it absolute? false
Is it hidden? false
What is its absolute path? /home/liang/book/./image/us.gif
What is its canonical path? /home/liang/book/image/us.gif
What is its name? us.gif
What is its path? ./image/us.gif
When was it last modified? Wed Jan 23 11:00:14 EST 2002
What is the path separator? :
What is the name separator? /
```

Examples

UseFile

DirectorySize

UseFilenameFilter

Text I/O

A <u>File</u> object encapsulates the properties of a file or a path, but does not contain the methods for reading/writing data from/to a file. In order to perform I/O, you need to create objects using appropriate Java I/O classes.

The objects contain the methods for reading/writing data from/to a file.

Read/write strings and numeric values from/to a text file using the <u>Scanner</u> and <u>PrintWriter</u> classes.

Writing Data Using PrintWriter

java.io.PrintWriter

+PrintWriter(filename: String)

+print(s: String): void

+print(c: char): void

+print(cArray: char[]): void

+print(i: int): void

+print(1: long): void

+print(f: float): void

+print(d: double): void

+print(b: boolean): void

Also contains the overloaded println methods.

Also contains the overloaded printf methods.

Creates a PrintWriter for the specified file.

Writes a string.

Writes a character.

Writes an array of character.

Writes an int value.

Writes a long value.

Writes a float value.

Writes a double value.

Writes a boolean value.

A println method acts like a print method; additionally it prints a line separator. The line separator string is defined by the system. It is \r\n on Windows and \n on Unix.

The printf method was introduced in §3.6, "Formatting Console Output and Strings."

Try-with-resources

Programmers often forget to close the file. JDK 7 provides the followings new try-with-resources syntax that automatically closes the files.

```
try (declare and create resources) {
  Use the resource to process the file;
}
```

WriteData

WriteDataWithAutoClose

Reading Data Using Scanner

java.util.Scanner

+Scanner(source: File)

+Scanner(source: String)

+close()

+hasNext(): boolean

+next(): String

+nextByte(): byte

+nextShort(): short

+nextInt(): int

+nextLong(): long

+nextFloat(): float

+nextDouble(): double

+useDelimiter(pattern: String):

Scanner

Creates a Scanner object to read data from the specified file.

Creates a Scanner object to read data from the specified string.

Closes this scanner.

Returns true if this scanner has another token in its input.

Returns next token as a string.

Returns next token as a byte.

Returns next token as a short.

Returns next token as an int.

Returns next token as a long.

Returns next token as a float.

Returns next token as a double.

Sets this scanner's delimiting pattern.

<u>ReadData</u>

Employee and TextFileTest

Problem: Replacing Text

Write a class named <u>ReplaceText</u> that replaces a string in a text file with a new string. The filename and strings are passed as command-line arguments as follows:

java ReplaceText sourceFile targetFile oldString newString

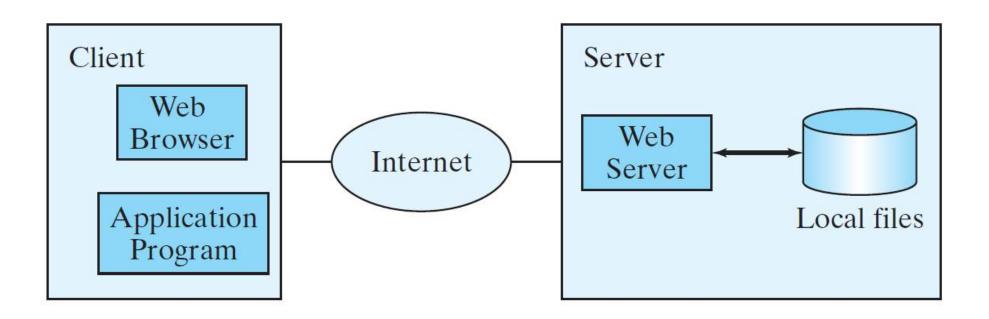

For example, invoking

java ReplaceText FormatString.java t.txt StringBuilder StringBuffer replaces all the occurrences of <u>StringBuilder</u> by <u>StringBuffer</u> in FormatString.java and saves the new file in t.txt.

ReplaceText

Reading Data from the Web

Just like you can read data from a file on your computer, you can read data from a file on the Web.

Reading Data from the Web

URL url = new URL("https://www.bupt.edu.cn");

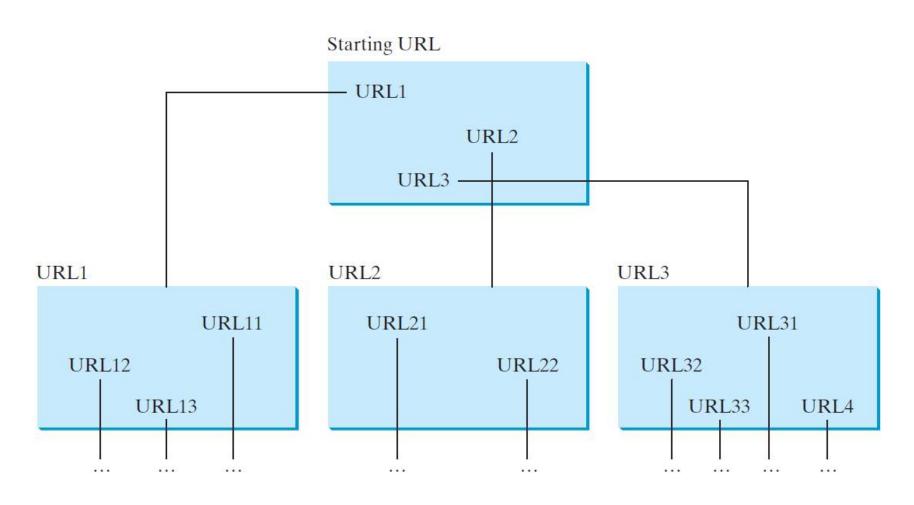

After a URL object is created, you can use the **openStream()** method defined in the URL class to open an input stream and use this stream to create a **Scanner** object as follows:

Scanner input = **new** Scanner(url.openStream());

ReadFileFromURL

Case Study: Web Crawler

This case study develops a program that travels the Web by following hyperlinks.

Case Study: Web Crawler

The program follows the URLs to traverse the Web. To assure that each URL is traversed only once, the program maintains two lists of URLs. One list stores the URLs pending for traversing and the other stores the URLs that have already been traversed.:

Case Study: Web Crawler

```
Add the starting URL to a list named listOfPendingURLs;
while listOfPendingURLs is not empty {
    Remove a URL from listOfPendingURLs;
    if this URL is not in listOfTraversedURLs {
        Add it to listOfTraversedURLs;
        Display this URL;
        Exit the while loop when the size of S is equal to 100.
        Read the page from this URL and for each URL contained in the page {
            Add it to listOfPendingURLs if it is not is listOfTraversedURLs;
        }
    }
}
```

WebCrawler
